A RE-EVALUATION TO STUDY THE STATUS OF THE
AHLYNGASTER SIRM STOCKS IN THE
 INSHORE WESTERN AROUND NEGOMBO, SRI LANKA

W.P.N. Karunasinghe and J. Wijeratne *
 National Aquatic Resources Agency, Colombo
 * University of Kelaniya

Using the available information on growth parameter estimates and length frequency distributions of Ahlyngaster sirm catch curves were designed for three consecutive periods. The total mortalities estimated from the above were 3.17, 3.11 and 2.98 for the periods 1984/85, 1985/86 and 1986/87 respectively.

A regression analysis of the total mortality vs total effort in the factory fishery; the above information together with some historical data gave the natural mortality at the intercept which was 2.06%.

SECTION D

The natural mortality estimate was used in the calculation of the exploitation rates during the study period and for the recalculations of the same with the historical data (*).

These estimates are summarized below.

<u>Period</u>	<u>Exploitation Rate</u>
1984/85	.350
1985/86	.340
1986/87	.310
1980/81 *	.313 *
1983/84 *	.325 *

Equipped with these information a management strategy is suggested here.
